

MDX-101 Phase II Study Summary

SYNTHETIC DEMO · NOT FOR CLINICAL USE

STUDY DESIGN

This fictional phase II study enrolled 120 adults with Example Syndrome. Participants were randomized 1:1 to MDX-101 or placebo for 12 weeks. The study was double-blind and conducted at eight simulated sites.

The primary endpoint was change from baseline in the Example Symptom Score at week 12. Secondary endpoints included response rate, quality of life, and treatment-emergent adverse events.

EFFICACY RESULTS

At week 12, the fictional mean reduction in Example Symptom Score was 8.4 points in the MDX-101 group and 3.1 points in the placebo group. The estimated between-group difference was 5.3 points (95% confidence interval 3.8 to 6.8).

A predefined response was observed in 62% of MDX-101 participants and 34% of placebo participants. These values exist only to test retrieval and citation behavior.

SAFETY RESULTS

The most frequently recorded fictional adverse events with MDX-101 were nausea (12%), headache (9%), and fatigue (7%). One serious adverse event occurred in each study group; neither was assessed as related to study treatment. No deaths were reported.

The simulated dataset is too small and too short to establish clinical safety. It must never be used for treatment decisions.
